## 2 Demand Fill Optimisation

1.  $x_o$  = Options
2.  $x_s$  = Random selection from options ( $x_o$ )
3.  $x_p$  = Problem to solve, which is the column sum of  $x_s$
4. Solve it. Solve knowing only  $x_p$  and  $x_o$ . Being blind to  $x_s$

Think of each column as a product and each row as an option for how much of each product. Thinking possible pallet configurations or possible cattle carcasse breakdowns makes these options more understandable.

```

nn=:4

### 3 Profit Optimisation

This is very similar to the demand fill optimisation example. Except with profit we want to maximise plus explicit weights are now needed. For example a product may have a gross profit of \$4 per unit when there is demand but may need to sell at a marked down price thereafter and may instead make a loss of \$1 per unit from that point on. It is weights like these that we are interested in when considering profit optimisation models.

Below we use a simple example. That us humans can quickly and easily solve. The approach below highlights the importance of this algorithm's ability to loop through previous solves to give it a chance to find a better solution to the problem after the first passthrough.

```

]<x0=(3 3) $ 2 0 0 1 1 0 1 0 1

|   |   |   |
|---|---|---|
| 2 | 0 | 0 |
| 1 | 1 | 0 |
| 1 | 0 | 1 |

]xp=:4 2 2
4 2 2
]<xt=(4,3) $ 0 NB. start with all zeros

## 4 The aaaabbbcca problem

I read a post recently by a software developer that ‘most candidates cannot solve this interview problem’:

Input: “aaaabbbcca”

Output: [(“a”,4),(“b”,3),(“c”,2),(“a”,1)]

J solution:

```
>({. ; #) each {{y <;.1~ 1, ~:/"1] 2 ]\ a. i. y}} 'aaaabbbcca'
```

a	4
b	3
c	2
a	1

## 5 Two Sum

From leetcode: <https://leetcode.com/problems/two-sum/>

Given an array of integers `nums` and an integer `target`, return indices of the two numbers such that they add up to `target`.

You may assume that each input would have exactly one solution, and you may not use the same element twice.

You can return the answer in any order.

Example 1:

Input: `nums = [2,7,11,15]`, `target = 9` Output: `[0,1]` Explanation: Because `nums[0] + nums[1] == 9`, we return `[0, 1]`. Example 2:

Input: `nums = [3,2,4]`, `target = 6` Output: `[1,2]` Example 3:

Input: `nums = [3,3]`, `target = 6` Output: `[0,1]`

Such a simple problem to solve using loops but I was interested in how to solve this problem in a loopless manner.

```
twosum=: 4 : '{. 4 $. $. x = (= i. # y) + +/~ y'
9 twosum 2 7 11 15
0 1
6 twosum 3 2 4
1 2
6 twosum 3 3
0 1
```
